**Notes:**
COPC = constituent of potential concern
dw = dry weight
EPC = exposure point concentration
kg = kilogram
kg dw/kg-day = kilograms dry weight per kilograms per day
LOAEL = lowest observed adverse effect level
mg/kg = milligram per kilogram
mg/L = milligram per liter
NOAEL = no observed adverse effect level
OU = Operable Unit
tPCB = total polychlorinated biphenyl
TRV = toxicity reference value
**Bold indicates hazard quotients greater than 1**

**Notes:**
COPC = constituent of potential concern
dw = dry weight
EPC = exposure point concentration
kg = kilogram
kg dw/kg-day = kilograms dry weight per kilograms per day
LOAEL = lowest observed adverse effect level
mg/kg = milligram per kilogram
mg/L = milligram per liter
NOAEL = no observed adverse effect level
OU = Operable Unit
tPCB = total polychlorinated biphenyl
TRV = toxicity reference value
**Bold indicates hazard quotients greater than 1**

**Notes:**
COPC = constituent of potential concern
dw = dry weight
EPC = exposure point concentration
kg = kilogram
kg dw/kg-day = kilogram dry weight per kilogram per day
LOAEL = lowest observed adverse effect level
mg/kg = milligram per kilogram
mg/L = milligram per liter
NOAEL = no observed adverse effect level
OU = Operable Unit
tPCB = total polychlorinated biphenyl
TRV = toxicity reference value
**Bold indicates hazard quotients greater than 1**

**Notes:**
COPC = constituent of potential concern
dw = dry weight
EPC = exposure point concentration
kg = kilogram
kg dw/kg-day = kilograms dry weight per kilograms per day
LOAEL = lowest observed adverse effect level
mg/kg = milligram per kilogram
mg/L = milligram per liter
NOAEL = no observed adverse effect level
OU = Operable Unit
tPCB = total polychlorinated biphenyl
TRV = toxicity reference value
**Bold indicates hazard quotients greater than 1**

**Notes:**
COPC = constituent of potential concern
dw = dry weight
EPC = exposure point concentration
kg = kilogram
kg dw/kg-day = kilograms dry weight per kilograms per day
LOAEL = lowest observed adverse effect level
mg/kg = milligram per kilogram
mg/L = milligram per liter
NOAEL = no observed adverse effect level
OU = Operable Unit
tPCB = total polychlorinated biphenyl
TRV = toxicity reference value
**Bold indicates hazard quotients greater than 1**

**Notes:**

COPC = constituent of potential concern
d/kg ww = days per kilogram wet weight
EPC = exposure point concentration
LOAEL = lowest observed adverse effect level
mg/kg dw = milligram per kilogram dry weight
-- = not applicable
NA = not available
NOAEL = no observed adverse effect level
OU = Operable Unit
tPCB = total polychlorinated biphenyl
Tco = transfer coefficient

**Bold indicates hazard quotients greater than 1**

**Notes:**
COPC = constituent of potential concern
dw = dry weight
EPC = exposure point concentration
kg = kilogram
kg dw/kg-day = kilograms dry weight per kilograms per day
LOAEL = lowest observed adverse effect level
mg/kg = milligram per kilogram
mg/L = milligram per liter
NOAEL = no observed adverse effect level
OU = Operable Unit
tPCB = total polychlorinated biphenyl
TRV = toxicity reference value
**Bold indicates hazard quotients greater than 1**

**Notes:**
COPC = constituent of potential concern
dw = dry weight
EPC = exposure point concentration
kg = kilogram
kg dw/kg-day = kilograms dry weight per kilograms per day
LOAEL = lowest observed adverse effect level
mg/kg = milligram per kilogram
mg/L = milligram per liter
NOAEL = no observed adverse effect level
OU = Operable Unit
tPCB = total polychlorinated biphenyl
TRV = toxicity reference value
**Bold indicates hazard quotients greater than 1**

**Notes:**
COPC = constituent of potential concern
dw = dry weight
EPC = exposure point concentration
kg = kilogram
kg dw/kg-day = kilograms dry weight per kilograms per day
LOAEL = lowest observed adverse effect level
mg/kg = milligram per kilogram
mg/L = milligram per liter
NOAEL = no observed adverse effect level
OU = Operable Unit
tPCB = total polychlorinated biphenyl
TRV = toxicity reference value
**Bold indicates hazard quotients greater than 1**

**Notes:**
COPC = constituent of potential concern
dw = dry weight
EPC = exposure point concentration
kg = kilogram
kg dw/kg-day = kilograms dry weight per kilograms per day
LOAEL = lowest observed adverse effect level
mg/kg = milligram per kilogram
mg/L = milligram per liter
NOAEL = no observed adverse effect level
OU = Operable Unit
tPCB = total polychlorinated biphenyl
TRV = toxicity reference value
**Bold indicates hazard quotients greater than 1**

**Notes:**
COPC = constituent of potential concern
dw = dry weight
EPC = exposure point concentration
kg = kilogram
kg dw/kg-day = kilograms dry weight per kilograms per day
LOAEL = lowest observed adverse effect level
mg/kg = milligram per kilogram
mg/L = milligram per liter
NOAEL = no observed adverse effect level
OU = Operable Unit
tPCB = total polychlorinated biphenyl
TRV = toxicity reference value
**Bold indicates hazard quotients greater than 1**

**Table E3-184**

**Wildlife Risk Calculations Based on Measured Tissue and Dietary Toxicity Reference Values for Terrestrial Receptors**

**LAA**

**Anniston PCB Site, Anniston, Alabama**

| Terrestrial Receptors | COPC | Soil EPC (mg/kg) | Water EPC (mg/L) | Percent Diet (%) | | | | | | | Measured Tissue (mg/kg dry weight) | | | | Body Weight (kg) |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| | | | | Terrestrial Plants | Terrestrial Insects | Worms | Terrestrial Spiders / Detritivores | Riparian Spiders / Detritivores | Small Mammals | Soil | Terrestrial Plants | Terrestrial Insects | Worms / Spiders / Detritivores | Small Mammals | Body Weight (kg) |

**Notes:**
COPC = constituent of potential concer
dw = dry weight
EPC = exposure point concentration
kg = kilogram
kg dw/kg-day = kilograms dry weight pe
LOAEL = lowest observed adverse effe
mg/kg = milligram per kilogram
mg/L = milligram per liter
NOAEL = no observed adverse effect l
OU = Operable Unit
tPCB = total polychlorinated biphenyl
TRV = toxicity reference value
**Bold indicates hazard quotients grea**

**Table E3-185**

**Wildlife Risk Calculations Based on Measured Tissue and Dietary Toxicity Reference Values for Aquatic+Terrestrial Receptors**

**LAA**

**Anniston PCB Site, Anniston, Alabama**

| Aquatic Receptors | COPC | Soil EPC (mg/kg) | Sediment EPC (mg/kg) | Water EPC (mg/L) | Percent Diet (%) | | | | | | | |
|---|---|---|---|---|---|---|---|---|---|---|---|---|

**Notes:**
COPC = constituent of potential concern
dw = dry weight
EPC = exposure point concentration
kg = kilogram
kg dw/kg-day = kilograms dry weight per kilograms per day
LOAEL = lowest observed adverse effect level
mg/kg = milligram per kilogram
mg/L = milligram per liter
NOAEL = no observed adverse effect level
OU = Operable Unit
tPCB = total polychlorinated biphenyl
TRV = toxicity reference value
**Bold indicates hazard quotients greater than 1**

**Notes:**
COPC = constituent of potential concern
dw = dry weight
EPC = exposure point concentration
kg = kilogram
kg dw/kg-day = kilograms dry weight per kilograms per day
LOAEL = lowest observed adverse effect level
mg/kg = milligram per kilogram
mg/L = milligram per liter
NOAEL = no observed adverse effect level
OU = Operable Unit
tPCB = total polychlorinated biphenyl
TRV = toxicity reference value
**Bold indicates hazard quotients greater than 1**

# 1 INTRODUCTION

In October 2005, Solutia Inc. and Pharmacia LLC completed a *Screening Level Ecological Risk Assessment for Operable Unit 4* (OU-4 SLERA; Blasland, Bouck, & Lee [BBL] 2005) at the Anniston Polychlorinated Biphenyl (PCB) Site (the Site). The SLERA concluded that exposure pathways for persistent bioaccumulative compounds exist for organisms that obtain their food from Choccolocco and lower Snow Creeks and their associated floodplains, and a baseline ecological risk assessment (BERA) would be required. Sediment and diet were identified as the primary pathways for exposure of fish, invertebrates, and wildlife to persistent bioaccumulative compounds. In addition, the surface soil pathway was concluded to be complete for passerine birds, reptiles, amphibians, omnivorous and carnivorous mammals, and raptors frequenting the floodplain areas.

The United States Environmental Protection Agency (USEPA) has requested consideration of potential risk associated with several constituents in addition to PCBs at OU-4, including risk from exposure to polychlorinated dibenzodioxins (PCDDs) and polychlorinated dibenzofurans (PCDFs) as 2,3,7,8-tetrachlorodibenzo-*p*-dioxin (TCDD, or dioxin) toxic equivalents (TEQs). This *Dioxin Toxic Equivalent Assessment* included as an appendix to the *Baseline Ecological Risk Assessment for Operable Unit 4* (OU-4 BERA) evaluates dioxin-like compounds (DLCs), including PCDD/PCDF and dioxin-like PCB (DL-PCB) congeners, that contribute to TEQ concentrations in OU-4. Food web modeling and toxicity reference values (TRVs) from the scientific literature were used to calculate hazard quotients (HQs) for TEQs. Additionally, tissue-based HQs were calculated for fish.

The exposure and effects assumptions referenced in this appendix are consistent with the assumptions for other constituents of potential concern (COPCs) evaluated in the OU-4 BERA, with the following exceptions: 1) risks were estimated using no observed adverse effect level (NOAEL) TRVs only; 2) literature-derived bioaccumulation factors (BAFs) were used for terrestrial invertebrates due to lack of site-specific data; and 3) bird egg HQs were not calculated due to the high degree of uncertainty in that evaluation (described below in Section 5). Congener-specific BAFs were used to estimate prey tissue exposure point concentrations (EPCs). The same wildlife receptors were evaluated in this TEQ assessment and the OU-4 BERA, with the exception of benthic invertebrates. Benthic invertebrates are believed to lack a functional aryl hydrocarbon receptor (AHR) and studies on invertebrates, while limited, indicate they are not susceptible to the effects of dioxin (Davies 1999). The general methodology employed to estimate risk using food web modeling is also consistent with that used to calculate HQs for other COPCs in the OU-4 BERA. An evaluation of OU-4 relative to background conditions is also provided herein. Because of the small dataset available and the use of NOAEL TRVs, this TEQ assessment is considered to be equivalent to a screening level estimation of risk, and the resulting risk estimates have a large degree of associated uncertainty, related primarily to estimation of bioaccumulation of DLCs into biotic tissues.

## 1.1 Approach to Calculating TEQ

TCDD and PCDDs/PCDFs are structurally and toxicologically-related halogenated aromatic hydrocarbons that have a common mechanism of action, involving binding of the chemicals to the AHR. USEPA (2008) recommends that the TEQ component mixture method be used to evaluate ecological risks posed by these compounds, using TCDD as the index chemical. Therefore, ecological hazards associated with

exposure to PCDDs/PCDFs are evaluated as TCDD TEQs throughout this assessment. Table F-1 presents summary statistics for PCDD/PCDF and DL-PCB congeners, as well as PCDD/PCDF, DL-PCB, and total (PCDD/PCDF + DL-PCB) TEQs for Choccolocco Creek sediment. Surface soil summary statistics for congeners and TEQs for the floodplain areas are presented in Table F-2.

TEQs were calculated using the avian, mammalian, and fish toxic equivalency factors (TEFs) from the World Health Organization (Van den Berg et al. 1998 and 2006, as cited in USEPA 2008). TEFs (reproduced from USEPA 2008 and presented in Table F-3) are used to equate the potential toxicity of each PCDD/PCDF congener based on its relative potency to TCDD. The concentration of each congener is multiplied by its TEF, resulting in a TCDD toxic equivalent concentration (i.e., the TEQ). TEQ values for each of the congeners are then summed to derive a total TEQ for each sample. In this assessment, there are three sets of TEFs (mammalian, avian, and fish); therefore, each sediment or soil sample has three TEQ values, depending on the TEFs used in the calculation. For example, the mammalian-derived soil TEQ is used to assess risks to mammalian receptors while the avian soil TEQ concentration is used for bird species.

While PCDDs/PCDFs were identified by USEPA as COPCs, it is important to clarify that this class of compounds does not include DL-PCBs. However, DL-PCBs are often included in the calculation of a TEQ, although there is a substantial amount of uncertainty regarding the use of the TEQ methodology for PCBs. This is particularly true when assessing risks to ecological receptors (Moore et al. 2012). Furthermore, the most significant PCB congeners in terms of “dioxin-like potency,” and therefore significant contributors to the TEQ, are the non-ortho substituted congeners: PCB-77, PCB-81, PCB-126, and PCB-169. These congeners were infrequently detected (PCB-77 and PCB-126) or not detected at all (PCB-81 and PCB-169) in OU-4 floodplain soil and sediment (Appendix E). As evidence of the infrequent nature of the occurrence of these congeners, none of the non-ortho substituted congeners were used in the quantitative estimates of risk for the *OU-4 Human Health Risk Assessment* (HHRA; Avatar 2013). In the HHRA, USEPA concluded that “a regression analysis performed on congeners with low FODs [frequencies of detection] would result in very uncertain predicted congener values, and because of this, only data from the [ortho-substituted] PCB-105, PCB-118, and PCB-156 were included in the analysis” (Avatar 2013).

Thus, inclusion of DL-PCBs in the TEQ analysis, particularly the non-ortho substituted congeners, results in a “very uncertain” estimate of TEQ sediment and soil concentrations. However, although exposure to PCBs is already being assessed as part of the OU-4 BERA, USEPA requested that TEQs be calculated both with and without the inclusion of DL-PCBs. The resulting soil and sediment TEQ concentrations (for PCDD/PCDF TEQ, DL-PCB TEQ, and total TEQ) are provided in Tables F-1 and F-2.

## 1.2 Document Organization

The potential ecological risks posed by PCDDs/PCDFs in sediment and soil are evaluated herein via an assessment that uses the TEQ approach described above. HQs for TEQs were calculated to provide a preliminary risk estimate for resident ecological receptor exposure to PCDDs/PCDFs and DL-PCBs and to provide information to risk managers regarding the need for further ecological investigation related to the presence of PCDDs/PCDFs at OU-4. This assessment includes:

- Exposure Assessment: Derivation of congener-specific BAFs and calculation of EPCs (Section 2)

- Toxicity Assessment: Review of the literature to derive appropriate TEQ-based TRVs for representative ecological receptors (i.e., birds, mammals, and fish) (Section 3)
- OU-4 TEQ Risk Estimation: Calculation of NOAEL HQs and Background Evaluation (Section 4)
- An analysis of the uncertainties associated with this assessment (Section 5)
- References cited (Section 6)

# 2 EXPOSURE ASSESSMENT

Food web modeling was used to calculate average dietary doses (ADDs) for PCDD/PCDF TEQ, DL-PCB TEQ, and total TEQ. Exposure assumptions used in the models are described in this section. Wildlife receptors evaluated in the OU-4 BERA and in this TEQ assessment include fish, eight mammals (white-tailed deer [*Odocoileus virginianus*], short-tailed shrew [*Blarina brevicauda*], raccoon [*Procyon lotor*], red fox [*Vulpes vulpes*], long-tailed weasel [*Mustela frenata*], little brown bat [*Myotis lucifugus*], American mink [*Neovison vison*], and river otter [*Lontra canadensis*]), and nine bird species (mourning dove [*Zenaida macroura*], blue jay [*Cyanocitta cristana*], Carolina wren [*Thryothorus ludovicianus*], red-tailed hawk [*Buteo jamaicensis*], spotted sandpiper [*Actitis macularius*] tree swallow *[Tachycineta bicolor*], belted kingfisher [*Megaceryle alcyon*], great blue heron [*Ardea Herodias*], and American osprey [*Pandion haliaetus*]).

For each receptor, the ADDs were calculated according to the USEPA dietary dose model, as follows:

$$ADD_{pot} = [\sum_{k-1}^{n}(C_k \times FR_k \times NIR_k) + (NIR_s \times COPC_s \times DF_s)] \times SUF$$

Where:

| | |
|---|---|
| $ADD_{pot}$ | Potential average daily dose (nanograms COPC per kilogram body weight per day [ng/kg BW-d]) |
| n | Number of food types |
| $C_k$ | COPC concentration in the kth food type (nanograms per kilogram dry weight [ng/kg dw]). |
| $FR_k$ | Dietary fraction of intake of the kth food type |
| $NIR_k$ | Normalized ingestion rate of the kth food type (kilograms of dry weight of food ingested per kilogram of body weight per day [kg dw/kg BW-d]) |
| $NIR_s$ | Normalized ingestion rate of soil or sediment (kilograms of dry weight of soil/sediment ingested per kilogram of body weight per day [kg dw/kg BW-d]) |
| $COPC_s$ | Exposure Point Concentration in soil/sediment (s) (ng/kg dw) |
| $DF_s$ | Dietary fraction of soil/sediment ingested (range 0 to 1.0) |
| SUF | Site use factor (assumed to be 100%); see Section 4.5.4 of the OU-4 BERA for definition |

Ecological receptors and exposure parameters (e.g., wildlife food ingestion rates, body weights, dietary proportions) used in this assessment are summarized in the OU-4 BERA and are reproduced in Tables F-4a and F-4b for birds and mammals, respectively. Tables F-5a and F-5b provide multiple dietary composition scenarios for specific birds and mammals, respectively. BAFs necessary to estimate prey tissue TEQ concentrations, as well as biotic and abiotic EPCs used in the food web models are presented below.

## 2.1 Calculation of Congener-Specific Bioaccumulation Factors

BAFs were calculated using site data for individual PCDD/PCDF and DL-PCB congeners using methodology described in Section 4.4 of the OU-4 BERA, with exceptions noted below. The congener-specific BAF calculations, provided in Attachment F1, were used to estimate PCDD/PCDF TEQs, DL-PCB TEQs, and total TEQs (including DL-PCBs) in receptor food items in the food web models, as described below.

### 2.1.1 Site-Specific BAFs and Modeled Prey Tissue Concentrations

BAFs were calculated using methodology similar to that for other COPCs evaluated in the OU-4 BERA, which is described in detail in Appendix B. Briefly, soil/sediment and biota samples were grouped by biological sampling area (BSA). Because of the limited size of the BAF datasets for PCDD/PCDF and DL-PCB congeners, regression analysis and calculation of assessment area (AA) BAFs could not be conducted. As described in Attachment F1, site-wide median BAFs were calculated for individual PCDD/PCDF and DL-PCB congeners using OU-4 sediment, surface soil, and biota data. Detected and nondetect (ND) soil/sediment values within the BSAs were included in the BAF calculations. The mean abiotic media concentration was calculated for each BSA using Kaplan-Meier (KM) statistics to account for any ND results. Only detected concentrations in tissue were included in the BAF calculations. BAFs for individual tissue samples ($BAF_i$s) were calculated based on dry weight values (microgram per kilogram, dry weight [µg/kg, dw]) using the formula:

$$BAFi = \frac{C_{biota}}{C_{sed\ or\ soil}}$$

where:

$BAF_i$ Bioaccumulation factor for individual tissue samples (unitless)

$C_{biota}$ Individual sample congener concentration in biota (µg/kg, dw)

$C_{sed\ or\ soil}$ BSA-specific KM mean concentration in sediment or soil (µg/kg, dw)

The site-wide median of the $BAF_i$ values was selected as the congener-specific BAF for use in the food web model.

In some cases, data were not sufficient to calculate a site-wide median BAF based on data grouped from the same BSA. If a COPC was detected in OU-4 tissue, but data were lacking for soil/sediment in the same BSA, the site-wide average BAF ratio was calculated by dividing the average detected tissue concentration by the average KM mean soil or sediment concentrations in the BSAs. Thus, the site-wide median BAF is based on data grouped in each BSA, and the site-wide average BAF ratio was used when biotic and abiotic data from the same BSA are unavailable and is not based on data grouped by BSA. If a congener was never detected in OU-4 tissue, no BAF was selected and the congener was excluded from the TEQ calculations. As a result, exposure to PCDD/PCDF and DL-PCBs was evaluated based only on congeners detected in OU-4 prey tissues.

BAFs were calculated for each food item for the receptors of concern, including aquatic plants, aquatic emergent and flying insects, reptiles, amphibians, fish, aquatic benthic invertebrates (Odonata larvae),

crayfish, molluscs, small mammals, and terrestrial plants. The selected BAFs are summarized in Table F-6 (refer to Attachment F1 for further discussion of the derivation of these values).

For aquatic oligochaetes, tissue data for PCDDs/PCDFs and DL-PCBs were not available. Consistent with the approach in the OU-4 BERA for non-mercury metals, BAFs for aquatic oligochaetes were based on benthic invertebrate (Odonata) tissue.

Because site-specific data were not available, BAFs for terrestrial invertebrates (grasshoppers/crickets, spiders, and earthworms) were based on literature values. For these prey tissues, BAFs were based on PCDD/PCDF uptake by earthworms from a study by Fagervold et al. (2010). The congener-specific earthworm BAFs (Table F-7) were used to estimate tissue TEQ concentrations.

The selected BAFs were used along with avian, mammalian, and fish TEFs from the World Health Organization (Van den Berg et al. 1998 and 2006, as cited in USEPA 2008) to estimate TEQ concentrations in prey tissues. The PCDD/PCDF TEQ, DL-PCB TEQ, and total TEQ were calculated for prey tissues using the following formula:

$MT_{TEQ}$ (ng/kg dw) = ($C_{sa}$ x $BAF_a$ x $TEF_a$) + ($C_{sb}$ x $BAF_b$ x $TEF_b$) + …($C_{si}$ x $BAF_i$ x $TEF_i$)

where:

| | |
|---|---|
| $MT_{TEQ}$ | Sample-specific modeled tissue TEQ concentration estimated using individual congener BAFs (ng/kg dw) |
| Cs | Concentration of PCDD/PCDF or DL-PCB congener in soil/sediment (ng/kg dw) |
| BAF | Congener-specific bioaccumulation factor (dw; unitless) |
| TEF | Congener-specific toxic equivalency factor (unitless) |

To reduce uncertainty in the prey tissue TEQ concentrations, tissue TEQ concentrations were estimated using the selected BAFs (Tables F-6 and F-7), assuming that all of the ND concentrations in soil/sediment are equal to zero. Uncertainty associated with this assumption is discussed in Section 5.5. Tissue TEQ concentrations were modeled from individual soil/sediment samples, and the 95 percent upper confidence limit (95%UCL) concentration was calculated from the sample-specific $MT_{TEQs}$ for each prey tissue type to represent EPCs. These modeled tissue TEQ concentrations (Attachment F2) were used in the dietary food web calculations and are summarized in Table F-8.

## 2.2 Calculation of Exposure Point Concentrations

EPCs for this TEQ screening assessment were based on 95%UCL concentrations calculated for each of the three OU-4 AAs (upper assessment area, middle assessment area, and lower assessment area [LAA), as defined in Section 2 of the OU-4 BERA. To evaluate receptors that may forage primarily in riparian areas along Choccolocco Creek, EPCs were also calculated for riparian areas, operationally defined by the 100-foot zone on each side of the creek, in each of the AAs, consistent with the approach used in the OU-4 BERA. The sample locations are presented in Figure F-1. Individual congener and TEQ data and corresponding AA and/or riparian area classifications for each sample are presented in Appendix E. Due to the small dataset available for sediment, EPCs for sediment and aquatic tissues are typically based on the maximum concentration in each AA. The EPCs were calculated for biotic and abiotic media, as described below.

### 2.2.1 Soil and Sediment EPCs

For estimation of incidental soil and sediment ingestion in the dietary food web models, avian, mammalian, and fish TEFs from the World Health Organization (Van den Berg et al. 1998 and 2006, as cited in USEPA 2008) were used to calculate TEQ concentrations for OU-4 data (Appendix E), as described in Section 1.1. For sediment, PCDD/PCDF congener data are available for 10 site samples and DL-PCB congener data are available for 12 site sediment samples. Total TEQ concentrations were calculated for 13 site samples, which include nine samples with both PCDD/PCDF and DL-PCB congeners, one sample with only PCDD/PCDF data, and three samples with only DL-PCB data. Additionally, three sediment samples collected from reference locations were analyzed for PCDD/PCDF and DL-PCB congeners (Appendix E). For soil, there are PCDD/PCDF and/or DL-PCB data for 102 surface soil samples (0 to 6 inches) collected from the floodplain[1]. PCDD/PCDF data are available for 100 soil samples, and DL-PCB data are available for 102 samples. Total TEQ concentrations were calculated for 102 samples. The sampling locations are described in the *Phase 2 Field Sampling Plan for Operable Unit 4* (Arcadis U.S., Inc. [Arcadis] 2010) and presented on Figure F-1. Sediment and soil TEQ concentrations were calculated using the available data for PCDDs/PCDFs and DL-PCBs. The resulting sediment TEQ concentrations are reported in Appendix E and summarized by AA in Table F-1. The soil TEQ concentrations are reported in Appendix E and summarized by AA in Table F-2.

Because several congeners routinely were not detected in the sediment and soil samples, a potential area of uncertainty associated with the TEQ calculation is the approach used to handle samples with non-detected (ND) values. For example, PCB-126 was detected in only 11 of 102 floodplain soil samples (10.8 %) and two of 12 sediment samples (16.7%). Two other non-ortho substituted congeners (PCB-81 and PCB-169) were not detected in floodplain soil or sediment samples. The treatment of samples with ND concentrations in the calculations can substantially affect the resulting TEQs. To address this uncertainty, bounding estimates of the TEQ concentrations were calculated. OU-4 sediment and surface soil mean TEQ concentrations were calculated with ND concentrations excluded (i.e., assuming that all of the ND concentrations were zero), with ND concentrations set at the reporting limit (RL), and with PCDDs/PCDFs set at the RL and PCBs at 0.5 x RL (Tables F-1 and F-2 for sediment and soil, respectively). The impact of the ND values is significant when DL-PCBs are included in the TEQ determination. For example, the LAA sediment total TEQ concentration (includes PCDDs, PCDFs and DL-PCBs) using the mammalian TEFs increases by more than 20-fold when 0.5 x RL is used as a substitute for ND PCDD/PCDF and DL-PCB congeners (EPCs based on maximum concentrations are 0.0185 micrograms per kilogram [µg/kg] and 0.392 µg/kg, respectively).

The TEQ EPCs calculated assuming NDs are equal to zero were selected for use in the dietary models. Uncertainty associated with this assumption is discussed in Section 5.

[1] Appendix E contains TEQ data for 106 samples, including seven samples listed as duplicates. Consistent with the BERA, duplicate samples were combined with their respective primary sample for calculation of EPCs. For three of these duplicate samples (located at C4N-37, C4N-53, and C4S-49), the primary sample was not analyzed for PCDD/PCDF or DL-PCB congeners. Therefore, these three samples were treated as primary samples for a total of 102 soil samples in the TEQ dataset.

### 2.2.2 Tissue EPCs

Modeled tissue EPCs for use in the dietary food web models and for calculation of fish tissue HQs were based on AA-wide 95%UCLs, and are presented in Table F-8. PCDD/PCDF, DL-PCB, and total TEQ concentrations were estimated using individual soil and sediment DLC congener data along with congener-specific BAFs for each tissue type, as described above in Section 2.1 and presented in Attachment F2. As noted above, modeled tissue TEQ concentrations were calculated assuming that ND congeners were zero. In a small number of samples (listed below), the modeled tissue TEQ concentration was zero because individual congeners were not detected in abiotic media. In these cases, the individual sample was excluded from the 95%UCL calculation so a calculated TEQ value of 0 did not affect the data distribution and subsequent upper confidence limit (UCL) calculation method. Thus, the number of samples included in the tissue EPCs may differ slightly from the number of soil/sediment samples available to estimate tissue concentrations. This is the case for two sediment samples (CU-006-03 and CU-010-01) and four soil samples (C7N-20, C7N-40, C7S-48, and C7S-57) that have estimated DL-PCB tissue TEQ concentrations of zero. Additionally, one sediment sample (CU-006-03) results in a predator fish PCDD/PCDF TEQ concentration of zero.

# 3 DERIVATION OF TEQ-BASED TRVS AND CRITICAL TISSUE CONCENTRATIONS

Food web modeling and TRVs from the scientific literature were used to calculate HQs for TEQs. Additionally, tissue-based HQs were calculated for fish using modeled fish tissue and critical tissue concentrations (CTCs).

In the derivation of TRVs and CTCs for this assessment, chronic studies were preferentially selected that link dietary exposure concentrations (or tissue residues in the case of fish) with effects that are associated with ecological consequences at the population level. Endpoints considered relevant to populations include significant reductions in survival, growth, or reproduction.

## 3.1 Avian Dietary TRV for Dioxin-Like Compounds

To derive the avian TRV, the literature was reviewed for studies that investigated the effects of dioxin (as TCDD or on a TEQ basis) on avian species. Laboratory and field studies have shown that some bird species are susceptible to PCDD/PCDF exposure, and effects documented include decreased egg production, reduced egg hatching, embryotoxicity, and deformities. Studies relevant to OU-4 ecological receptors are summarized below.

### 3.1.1 Tittabawassee River Study (Fredricks et al. 2011)

Fredricks et al. (2011) studied tree swallows exposed to DLCs along the Tittabawassee River near Midland, Michigan. These researchers observed that tree swallow hatching success and overall productivity through fledging were not statistically different between sites with PCDDs/PCDFs in sediment and floodplain soils and upstream reference areas.

Fredricks et al. (2011) conducted a hazard assessment for tree swallows using dietary TRVs derived from an intraperitoneal injection study conducted using ring-necked pheasants (Nosek et al. 1992). Fredricks et al. (2011) derived dietary TRVs from the Nosek et al. (1992) data by converting the weekly exposure at which adverse effects on pheasant fertility and hatching success were reported (1,000 nanograms of TCDD per kilogram body weight per week [ng/kg BW-week]) to a daily exposure of 140 ng TCDD/kg body weight per day (ng/kg BW-d). Fredricks et al. (2011) interpreted this to be the lowest observed adverse effect level (LOAEL). Adverse effects were not present at the next lowest daily dose (14 ng/kg BW-d), which was considered the NOAEL.

Fredricks et al. (2011) determined food web-based TEQ doses (34 to 630 ng/kg BW-d calculated from measured invertebrate residues) and bolus-based dietary doses (24 to 800 ng/kg BW-d) for tree swallows breeding in contaminated Tittabawassee River floodplains (Supplemental Data, Table S2 in the Fredricks et al. 2011 study). No effects on tree swallow hatching success and productivity were observed at the highest dose, 800 ng TCDD/kg BW-d; therefore, this can be considered an unbounded dietary NOAEL.

The estimated TEQ doses from the Fredricks et al. (2011) study (24 to 800 ng/kg BW-d) are greater than the NOAEL TRV derived from the Nosek et al. (1992) study (14 ng/kg BW-d), and the maximum dietary doses (630 and 800 ng/kg BW-d) are also greater than the LOAEL TRV (140 ng/kg BW-d), while the reference-area dietary exposures are lower than both TRVs. Despite exceeding the TRVs derived from

the Nosek et al. (1992) study, there were no statistically significant differences in population-level responses (i.e., overall productivity through fledging) between Tittabawassee River tree swallows and those from reference sites. This suggests the TRVs derived from the Nosek et al. (1992) pheasant study are overly conservative for tree swallows. This conclusion is supported by Fredricks et al. (2011), which states “TRVs based on intraperitoneal injections of TCDD in hen ring-necked pheasants would be expected to over-estimate effects thresholds for tree swallows.”

### 3.1.2 Woonasquatucket River Study (Custer et al. 2005)

In a field study by Custer et al. (2005) at the Woonasquatucket River in Rhode Island, PCCD/PCDF concentrations in eggs, diet, and nestlings and measures of reproductive success were compared to contaminated ponds (Allendale and Lyman) and a reference site (Greystone) over two years, 2000 to 2001. Tree swallows at the TCDD-contaminated Allendale and Lyman sites were exposed to and accumulated more TCDD than swallows at the Greystone reference site. The authors reported that approximately 90% of the TEQ was due to the presence of 2,3,7,8-TCDD, indicating that the Woonasquatucket River exposures were primarily from TCDD. A significant reduction in hatching success was observed at the Allendale site, but not at the Lyman site, compared to the Greystone reference area, despite TCDD concentrations of up to 119.5 ng/kg (121 ng TEQ/kg) in the diet of swallows at the Lyman site. Nestling survival was reduced at the Allendale pond in the year 2000 (at 72 ng TEQ/kg in diet), but was unaffected at all ponds in 2001 (maximum TEQ concentration in diet was 226 ng/kg), despite significant differences in PCDD/PCDF concentrations. The authors hypothesized that the nestling mortality observed in 2000 may have been due to a cold period and a dam breach that occurred at the Allendale pond that year (Custer et al. 2005); therefore, the data from 2000 were not relied upon for TRV derivation.

The following table provides the PCDD/PCDF concentrations in diet and TEQ calculations using the data from the Custer et al. (2005) study.

**Concentratons of PCCD/PCDFs in pooled diet samples at the Woonasquatucket River (ng/kg, wet weight)**

| Chemical | TEF | 2000 | | | | 2001 | | | | | | |

| TEQ | | | 72 | | 1 | | 226 | | 7 | | 121 | 140 |

Data from Custer et al. (2005)

The estimated TEQ concentration in diet for tree swallows at the Lyman site in 2001, when survival during the incubation and nestling periods was unaffected, was 121 ng/kg wet weight (ww); this can be considered the dietary NOAEL. Assuming that the moisture content of the invertebrate prey of tree swallows is 80 percent (%), a dry weight-based dietary NOAEL for TEQ of 605 ng/kg was calculated.[2] Using the body weight-normalized tree swallow ingestion rate of 0.24 kilograms (kg) of food per kg BW-d,[3] a dose-based TRV of 145 ng TEQ/kg BW-d was derived.

### 3.1.3 Avian Dietary NOAEL-Based TRV

The literature from field studies regarding the effects of TCDD on birds is inconsistent; some studies show no effects at even relatively high concentrations of TCDD in diet, while others show effects at lower levels of exposure. Laboratory studies in which PCDDs/PCDFs have been fed to avian species are limited. In the Tittabawassee River study by Fredricks et al. (2011), no significant differences were found in overall productivity between tree swallows from the study area as compared to reference areas at dietary doses as high as 800 ng TEQ/kg BW-d. In the Woonasquatucket River study by Custer et al. (2005), no adverse effects on hatching success or nestling period were observed at an estimated dietary dose of 145 ng TEQ/kg BW-d.

[2] 121 ng/kg ww ÷ 20% solids in diet = 605 ng/kg dw
[3] Refer to exposure parameters provided in Table F-4a.

The study by Custer et al. (2005) was selected as the basis of the NOAEL-based avian TRV (145 ng TEQ/kg BW-d) for the following reasons:

- The evaluation considered sensitive and population-relevant reproductive endpoints: hatching success and fledging.
- The study was conducted on tree swallow, a species that was selected as a representative receptor at OU-4.
- Custer et al. (2005) reported that nearly 90% of the TEQ in tree swallow eggs and nestling carcass samples was from a single congener—2,3,7,8-TCDD. Thus, this study is specific to the single congener used as the standard for the TEQ method (USEPA 2008).
- The NOAEL TRV derived from the Custer et al. (2005) study (145 ng/kg BW-d) is lower than the unbounded NOAEL TRV derived from the study by Fredricks et al. (2011) (800 ng/kg BW-d), and is therefore considered more conservative.

Similar to mammalian species, most, if not all, biochemical and toxic effects of TCDD and other DLCs in birds are thought to be mediated by the AHR. Data show a link between the adverse effects and a mode of action in which binding and activation of the AHR is the critical initiating event (Denison et al. 2011; Okey 2007). Farmahin et al. (2012, 2013) recently reported that the sensitivity of avian species to the toxic effects of DLCs varies up to 1,000-fold among species. Further, their research and that conducted by others (e.g., Head et al. 2008; Karchner et al. 2006) suggest that this variability has been associated with interspecies differences in the AHR 1 ligand binding domain (AHR1 LBD) sequence.

Farmahin et al. (2013) studied the AHR1 LBD sequences of 86 avian species, and classified birds into three major types based on their sensitivity to the toxic and biochemical effects of DLCs: chicken-like or Group 1 (most sensitive), pheasant-like or Group 2 (intermediate sensitivity, 6-fold lower than Group 1), and quail-like or Group 3 (least sensitive, 35-fold less sensitive than Group 1). Of the nine avian species selected for evaluation in the OU-4 BERA, eight were evaluated in the Farmahin et al. (2013) study—mourning dove, blue jay, red-tailed hawk, spotted sandpiper, tree swallow, belted kingfisher, great blue heron, and osprey. The mourning dove, blue jay, spotted sandpiper, and tree swallow were placed in Group 2 (intermediate sensitivity), while the red-tailed hawk, belted kingfisher, great blue heron, and osprey were assigned to Group 3 (least sensitive). The Carolina wren, an OU-4 receptor species, was not evaluated by Farmahin et al. (2013), but a related species, the house wren (*Troglodytes aedon*), was included in Group 2. None of the bird species included in the OU-4 BERA were classified as "most sensitive" or Group 1 in the Farmahin et al. (2013) study. This suggests that the Custer et al. (2005) study provides an appropriately protective TRV for Group 2 species, including the mourning dove, blue jay, spotted sandpiper, and tree swallow, but may be overly conservative for and overstate risks to Group 3 species in the assessment—the red-tailed hawk, belted kingfisher, great blue heron, and osprey.

## 3.2 Mammalian Dietary TRV for Dioxin-Like Compounds

As with avian species, the literature was reviewed for studies that evaluated the effects of dioxin (on a TCDD or TEQ basis) on mammals for the derivation of the mammalian TRV. Laboratory studies particularly on mice and rats have shown effects from dioxin exposure including immune system

suppression, increased hepatic porphyria, development of tumors, and reduced sex hormones and decreased fertility.

Previous studies of individual PCDD and PCDF congeners or their mixtures have demonstrated that mink are among the more sensitive mammalian species tested, with effects reported on reproduction, development, and morphological lesions of the jaw (Bursian et al. 2006; Heaton et al. 1995; Restum et al. 1998). Studies on mink jaw lesions suggest that this endpoint is considered a sentinel for adverse effects in mink populations (Ellick et al. 2012; Zwiernik et al. 2009). However, from a population impact perspective, adverse effects on reproduction and development are considered more relevant assessment endpoints. Mink are typically encountered in riparian ecosystems, and studies of mink are more environmentally relevant than those conducted on laboratory species such as mice or rats (e.g., Murray et al. 1979; DeVito et al. 1997), especially with compounds such as PCDDs/PCDFs, which exhibit a high degree of variability in sensitivity among mammalian species. Mink are expected to occur along Choccolocco Creek due to habitat availability, and this species provides a surrogate for the less-sensitive mammals at OU-4 that are being evaluated: white-tailed deer, short-tailed shrew, raccoon, red fox, long-tailed weasel, and little brown bat. The river otter, another OU-4 receptor species, is likely similar to mink in its sensitivity to DLCs, given that both species are semi-aquatic members of the Mustelidae family.

Numerous studies of mink demonstrate the toxicity of DLCs, including PCB-126, in this species. Often studies of these animals are conducted in which co-exposure to PCB-126 and TCDD exists (e.g., Restum et al. 1998), and discriminating the contribution of PCB-126 to the observed adverse effects is difficult if not impossible. Thus, in choosing the study for development of the TCDD-based TRV, one of the primary criterion was that the animals were not co-exposed to PCBs, particularly PCB-126. A recent study by Moore et al. (2012) satisfies this criterion and was selected as the basis for the mammalian TRV.

Moore et al. (2012) investigated the effect of TCDD, 2,3,4,7,8-pentachlorodibenzofuran (PeCDF), and 2,3,7,8-tetrachlorodibenzofuran (TCDF) on mink reproductive success, and offspring viability and growth. Nine adult female mink were assigned randomly to one of 13 dietary treatments: one control and four doses each of TCDD, PeCDF, and TCDF (2.1 to 8.4, 4 to 15, and 5.2 to 25 ng TEQ/kg BW-d, respectively). The mink were dosed from two months prior to breeding through weaning of offspring at six weeks of age. At least nine kits per treatment group were maintained on these diets through 27 weeks of age. No effects on litter size or viability of offspring were observed at any treatment level. In addition, no consistent effects on body mass or relative organ masses were observed. Therefore, this recent study by Moore et al. provides an unbounded NOAEL of 25 ng TEQ/kg BW-d, the highest dose at which no effects were observed. The authors also concluded that the lack of significant effects contrasts with effects reported for mink exposed to environmentally derived PCB mixtures with equivalent TCDD potencies, suggesting that it may be inappropriate to apply TRVs associated with PCB mixtures to animals exposed to TCDD.

Similarly, Zwiernik et al. (2009) exposed mink to TCDF in diet up to 240 ng TEQ/kg ww. These authors reported that doses as high as 30 ng TEQ/kg BW-d[4] did not affect reproduction and kit viability; although, body masses of offspring through 36 weeks of age were decreased compared to controls at various time points in the experiment. The results of this study are supported by a review by Blankenship et al. (2008), which indicated 242 ng TEQ/kg ww as the highest diet-based LOAEL for offspring weight.

[4] Dose calculated using the mink food ingestion rate of 0.125 kg/kg bw-d from Moore et al. (2012).

The study by Moore et al. (2012) was selected as the basis for the derivation of the mammalian TRV (25 ng TEQ/kg BW-d) for the following reasons:

- Mink are likely more sensitive to the effects of PCDDs/PCDFs than are most of the other representative mammalian receptors for OU-4 (see Appendix D for additional information regarding relative sensitivity of mammals): white-tailed deer, short-tailed shrew, raccoon, red fox, long-tailed weasel, and little brown bat. In addition, mink are likely similar to the river otter in sensitivity given that both are semi-aquatic members of the Mustelidae family. Therefore, the Moore et al. (2012) TRV should be adequately protective of these other receptors.
- Mink in this study were exposed only to constituents that are the focus of this assessment: TCDD and PCDDs/PCDFs.
- The study evaluated sensitive and population-relevant endpoints: litter size and viability of offspring.
- The NOAEL-based TRV is supported by the results of other studies in which dietary doses up to 30 ng TEQ/kg BW-d did not affect mink reproduction and kit viability (Zwiernik et al. 2009).

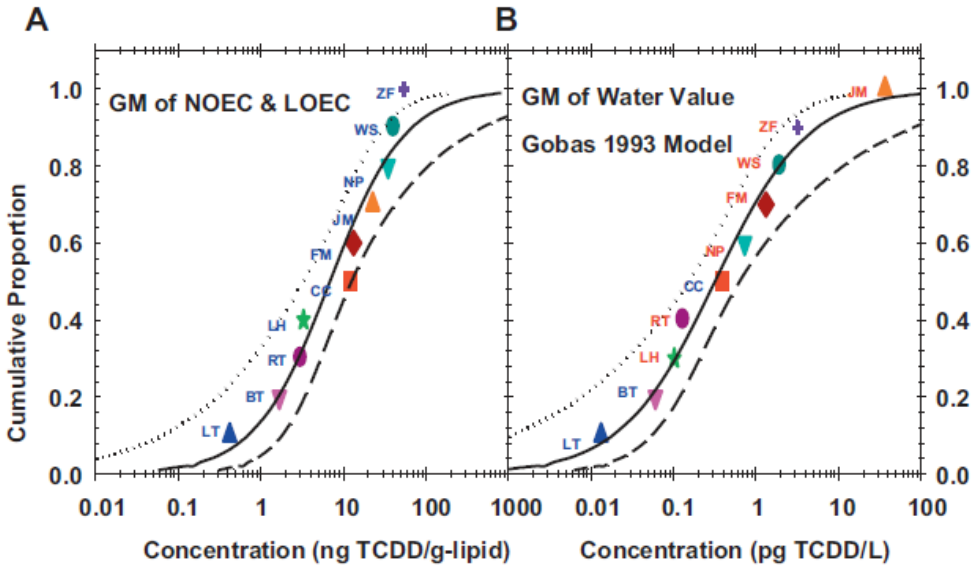
## 3.3 Fish CTC for Dioxin-Like Compounds

A study by Steevens et al. (2005), which establishes benchmark distributions for TCDD and TEQ effect concentrations in fish, was relied upon to develop a fish tissue-based CTC. Steevens et al. (2005) developed a residue effects distribution for fish eggs and embryos, the life stage that is most sensitive to AHR mediated toxicity. Steevens et al. (2005) compiled effects data for different fish species from the United States Army Corps of Engineers (USACE) Residue Effects Database (USACE 2004) and the USEPA Office of Research and Development Effect Residue Database (Jarvinen and Ankley 1999). Residues reported on a whole egg or embryo basis were combined into a species sensitivity distribution based on the geometric means of no observable effect residue (NOER) values and lowest observable effect residue (LOER) values; endpoints included significant reductions in survival, growth, or reproduction (Steevens et al. 2005).

Most of the studies included in the effects distribution were conducted for TCDD, and maternal uptake, transfer to eggs (including egg injection studies), and direct absorption exposure pathways were included in the distribution. Because of the lipophilicity of DLCs, effect residues of TCDD in fish eggs can be related to maternal tissue concentrations after lipid normalization. For nonpolar organic compounds, the ratio of chemical on a lipid-normalized basis was found to be approximately 1:1 egg to adult fish (Russell et al. 1999). Therefore, the egg and embryo effect levels generated from the Steevens et al. analysis (2005) can directly be used to interpret whole-body tissue residues for fish collected at OU-4.

Studies on lake trout (*Salvelinus namaycush*), brook trout (*Salvelinus fontinalis*), rainbow trout (*Oncorhynchus mykiss*), channel catfish (*Ictalurus punctatus*), lake herring (*Coregonus artedi*), fathead minnow (*Pimephales promelas*), Japanese medaka (*Oryzias latipes*), northern pike (*Esox lucius*), white sucker (*Catostomus commersonii*), and zebrafish (*Danio rerio*) were included in the species sensitivity distribution for TCDD, and tissue residue benchmarks were derived by Steevens et al. (2005) to be protective of fish populations. Mean, lower, and upper 95%UCL benchmarks were selected at different species protection levels (i.e., protective of 99, 97.5, 95, or 90% of fish species). The species sensitivity distribution developed by Steevens et al. (2005) incorporates residue effect data for lake trout and other

salmonids that are substantially lower (i.e., more highly sensitive) than residues associated with effects in the other, less-sensitive fish species. Inclusion of the salmonid species in the residue effects curve results in tissue residue benchmarks that are likely overprotective for other fish species. This has been illustrated by Sappington et al. (2011), who compared lethal residues associated with 50% mortality (LR50) among fish species using data from the Steevens et al. analysis (2005) (see figure below).



Fish sensitivity distribution for tissue residues ($LR_{50}$ values) and exposure concentrations ($LC_{50}$ values) for LT=lake trout, BT=brook trout, RT=rainbow trout, CC=channel catfish, LH=lake herring, FM=fathead minnow, JM=Japanese medaka, NP=northern pike, WS=white sucker, and ZF=zebrafish (reproduced from Sappington et al. 2011).

As indicated on the figure, trout are the most sensitive species to the effects of TCDD. Benthic, forage, and predator fish were collected from Choccolocco Creek. The fish species sampled and analyzed for TCDD in the OU-4 assessment include largescale stoneroller (*Campostoma oligolepis*), Alabama hog sucker (*Hypentelium etowanum)*, Alabama shiner (*Cyprinella callistia*), blacktail shiner (*Cyprinella venusta*), Coosa shiner (*Notropis xaenocephalus*), striped shiner (*Luxilus chrysocephalus*), silverstripe shiner (*Notropis stilbius*), blacktail redhorse (*Moxostoma poecilurum*), riffle minnow (*Phenacobius catostomus*), black-spotted topminnow (*Fundulus olivaceus*), spotted bass (*Micropterus punctulatus*), and large-mouth bass (*Micropterus salmoides*). While none of these species are represented in the distribution shown on the figure, it is expected that all of these species are less sensitive to the effects of TCDD than the highly sensitive salmonids. Therefore, the 90% species protection level from Steevens et al. (2005) should be sufficiently protective for the Choccolocco Creek fish species. Hence, the benchmark value of 2.2 ng TCDD/gram (g) lipid was selected as the CTC for fish. This value is based on the 95%UCL effects residue (based on the geometric mean of NOER and LOER values) from the Steevens et al. (2005) study.

To convert the lipid-based CTC to a dry weight basis for use with the dry weight BAFs, an adjustment for the fraction of lipid and a wet weight to dry weight conversion were needed. The mean lipid fraction for fish sampled from OU-4 and analyzed for PCDDs/PCDFs is 0.029; the maximum lipid fraction is 0.065, based on wet weight fish tissue concentrations. The average moisture content for fish tissue was assumed to be 75% (USEPA 1993). Two CTCs were calculated for fish, one using the mean lipid fraction

and one using the maximum (i.e., Scenarios 1 and 2) lipid fraction. The following formula was used to adjust the CTC from a lipid-basis to a dry-weight basis:

$$\text{CTC dw} = \text{CTC lipid} \times f\text{lipid} \times (100/100 - \%\ \text{moisture})$$

Where:

| | | |
|---|---|---|
| CTC | dw | Critical tissue concentration based on dry weight (ng/g BW, dw) |
| CTC | lipid | Lipid-normalized critical tissue concentration based on wet weight (ng/g lipid, ww) |
| *f*lipid | | Fraction lipid for OU-4 fish samples (g lipid/g bw, ww) |

The resulting fish tissue CTC values for the mean and maximum lipid scenarios are 255 ng/kg dw and 572 ng/kg dw, respectively. Because the fish TRV is based on a species sensitivity distribution that includes highly sensitive species such as salmonids, these values represent “safe” sediment TEQ concentrations that fish receptors could be exposed to without risk of adverse effects.

# 4 OU-4 TEQ RISK ESTIMATES

As noted above and consistent with the OU-4 BERA, dietary food web models were used to estimate risk for each representative wildlife receptor, including fish, eight mammals (white-tailed deer, short-tailed shrew, raccoon, red fox, long-tailed weasel, little brown bat, mink, and river otter), and nine bird species (mourning dove, blue jay, Carolina wren, red-tailed hawk, spotted sandpiper, tree swallow, belted kingfisher, great blue heron, and American osprey).

For the dietary HQs, congener-specific BAFs (Section 2.1) were used to estimate prey tissue TEQ concentrations. Soil/sediment and prey tissue TEQ EPCs were used to estimate TEQ ADDs, which were compared to the dietary TRVs selected in Section 3. The dietary HQs were calculated as follows:

$$Dietary\ HQ_x = \frac{ADD_{x_{pot}}}{Dietary\ TRV_x}$$

Where:

| | |
|---|---|
| Dietary $HQ_x$ | HQ for COPC "x" based on dietary exposure (unitless) |
| $ADD_{xpot}$ | potential ADD from COPC "x" (ng/kg BW-d) from Equation 2 (Section 2) |
| Dietary $TRV_x$ | dietary TRV for COPC "x" for avian- or mammalian-specified receptor (ng/kg BW-d; Section 3) |

Additionally, estimated TEQ concentrations in fish tissue were compared to tissue CTCs. Tissue-based HQs were calculated as follows:

$$Tissuex_i\ HQ_x = \frac{Tissuex_i\ EPC_x}{Tissuex_i\ CTC_x}$$

Where:

| | |
|---|---|
| $Tissue_i\ HQ_x$ | HQ for COPC "x" for tissue "i" (unitless) |
| $Tissue_i\ EPC_x$ | modeled EPC (Section 2.1) from COPC "x" (ng/kg dw), and |
| $Tissue_i\ CTC_x$ | tissue CTC for COPC "x" for tissue type (ng/kg dw) |

Figure F-2 summarizes the HQs based on modeled tissue TEQ concentrations. Due to uncertainties in the uptake, toxicity, and exposure terms included in the calculation, HQs are reported only to one significant digit in this TEQ assessment, consistent with presentation of HQs in the OU-4 BERA. For example, if the estimated HQ is 5.6, there is only enough confidence in the estimated HQ to report a value of 6. The HQs are presented on a toxic unit (TU) basis, with the PCDD/PCDF TEQ HQ and DL-PCB HQ summed to generate a total TEQ HQ for each receptor (denoted by the top of the stacked bar). The black dashes indicate the total TEQ HQ calculated directly using the total TEQ 95%UCL (or maximum) EPC. The total TEQ HQ calculated using the TU approach does not always match the total TEQ HQ

calculated using the 95%UCL soil and tissue EPC concentrations because the total TEQ 95%UCL concentrations are not equal to the sum of the 95%UCL PCDD/PCDF and 95%UCL DL-PCB soil and tissue concentrations. Uncertainties related to the presentation of TEQ HQs on a TU and direct calculation basis are discussed in Section 5. Complete HQ calculations are presented in Attachment F3.

Consistent with the interpretation of HQs in the OU-4 BERA, NOAEL HQs less than or equal to 1 indicate no unacceptable risk, as the NOAEL toxicity values represent a toxicological threshold below which there is high confidence in a finding of no unacceptable risk (i.e., risk is considered *de minimis*). NOAEL HQs greater than 1 indicate that risk is uncertain to wildlife populations and individuals.

## 4.1 Results for Avian Receptors

For all aquatic and terrestrial avian receptors, TEQ NOAEL HQs were less than or equal to 1 based on the AA-modeled EPCs with PCDD/PCDF TEQ or DL-PCB TEQ. For total TEQ HQs, all avian HQs were less than or equal to 1 when calculated on a TU basis or direct calculation basis except for Carolina wren (1 and 2). In the LAA, Carolina wren (1 and 2) had NOAEL total TEQ HQs equal to 2 when calculated directly using the total TEQ EPC; however, total TEQ HQs on a TU basis were equal to 1. The TU analysis and EPCs indicated that DL-PCBs are the primary contributor to the total TEQ HQs greater than 1. Uncertainty in the Carolina wren HQs is discussed in Section 5.4.1.

## 4.2 Results for Mammalian Receptors

For all aquatic and terrestrial mammalian receptors, TEQ NOAEL HQs were less than or equal to 1 based on the AA modeled EPCs with PCDD/PCDF TEQ, DL-PCB TEQ, or total TEQ (on a TU or direct calculation basis).

## 4.3 Results for Fish

For forage fish, bottom fish, predator fish, and all fish, TEQ NOAEL HQs were less than 1 based on the AA modeled EPCs with PCDD/PCDF TEQ, DL-PCB TEQ, or total TEQ (on a TU basis and direct calculation basis).

## 4.4 Consideration of Ambient TEQ Concentrations

PCDD/PCDFs are present in environmental media due to releases from both natural and anthropogenic sources and subsequent aerial transport and deposition. Thus, some proportion of TEQ concentrations in biotic and abiotic media in any particular location is due to ambient concentrations. Because DLCs elicit toxic effects at low concentrations, unacceptable risk can often be predicted at TEQ concentrations associated with ambient exposures. Consideration of the contribution of ambient, or “background”, TEQ concentrations is important when evaluating the potential for unacceptable risk at a site.

A formal background dataset for PCDD/PCDFs is not available for OU-4. However, limited PCDD/PCDF data are available from the OU-4 reference areas. Background PCDD/PCDF TEQ data are available in the literature as well. While OU-4 PCDD/PCDF concentrations appear to be somewhat greater than in

reference areas, the OU-4 PCDD/PCDF TEQ concentrations fall predominantly within the range of background soil TEQ concentrations reported by USEPA (2004), as described below.

PCDD/PCDF sediment data are available from three reference locations outside OU-4 that were evaluated as part of the BERA process. As presented in Table F-1, the mean sediment mammalian PCDD/PCDF TEQ concentrations in the OU-4 assessment areas (ranging from 0.00623 to 0.00924 µg/kg dw, depending on treatment of ND congeners) are greater than the mean sediment concentrations in the reference locations (0.000399 to 0.0012 µg/kg dw). This comparison is limited in utility however, due to the small sample size for both OU-4 (N=10) and reference (N=3) datasets. OU-4 reference PCDD/PCDF data are not available for soil.

As summarized in USEPA (2004), PCDD/PCDF TEQ concentrations in background soils range up to 0.057 µg/kg dw in North America (BC Environment 1995, USEPA 2001). The majority of OU-4 soil samples fall within this range. Only six of 106 samples (including six duplicates) exceed the background range for PCDD/PCDF TEQ (Table F-9) when calculated using either zero or one-half RL for NDs, and eight of 106 samples (including six duplicates) exceed the PCDD/PCDF TEQ background range when calculated using the full RL for NDs.

Note that the locations exceeding the background range for PCDD/PCDF TEQ are in the in the more downstream areas of OU-4 and are not located in areas associated with elevated PCB concentrations, such as in Snow Creek or the backwater areas of OU-4 (see OU-4 BERA Section 8).

Sediment PCDD/PCDF TEQ concentrations are all within the range of soil background (maximum value using full RL is 0.033 µg/kg dw.

Based on the available information, PCDD/PCDF TEQ concentrations in OU-4 are mostly consistent with background concentrations, except for a few locations in floodplain soil in the downstream reaches of Choccolocco Creek.

# 5 UNCERTAINTY ANALYSIS

As with any risk assessment, there is a degree of uncertainty inherent in the assumptions and calculations. Uncertainties in any risk assessment include natural variability in chemical concentrations, interspecies differences in sensitivity, errors in field and laboratory measurements of exposure and effects, incomplete knowledge regarding pathways and routes of exposure, and uncertainties associated with exposure models (USEPA 2008). For example, uncertainty associated with exposure models stems from the use of literature data for exposure parameters such as body weight, ingestion rate, and dietary composition for the receptors evaluated in the OU-4 BERA, and natural populations may exhibit considerable variability in these parameters. Exposure model uncertainty and several other areas of uncertainty described in the OU-4 BERA (refer to OU-4 BERA Section 6.2) are relevant to this TEQ assessment (e.g., derivation of BAFs). Several of the more significant areas that contribute to the uncertainty associated with the TEQ risk estimates are discussed below. These uncertainties may result in HQs that may under- or overestimate risks to OU-4 receptors.

## 5.1 Uncertainties Associated with TEQ Methodology

USEPA (2008) summarizes the uncertainties associated with TEFs and TEQ methodology. According to USEPA (2008), “While there are uncertainties associated with the application of the toxicity equivalence methodology, they are believed to be, in aggregate, less significant than those associated with other aspects of the risk assessment process and those associated with other approaches for assessing risks of dioxin-like chemicals. Uncertainties in the toxicity equivalence methodology are related to the assumptions and procedures used to derive the TEFs… as well as the relative potency data underlying these values.”

There is a high degree of uncertainty associated with including PCB congeners in the calculation of soil and sediment TEQ concentrations due to the unreliability of the TEFs for these compounds, particularly when assessing risks to ecological receptors. The most significant PCB congeners in terms of “dioxin-like potency,” and therefore significant contributors to the TEQ, are the non-ortho substituted congeners: PCB-77, PCB-81, PCB-126, and PCB-169. These congeners were sporadically detected (PCB-77 and PCB-126) or not detected at all (PCB-81 and PCB-169) in OU-4 floodplain soil and sediment. For example, PCB-126 was detected in only 11 of 102 floodplain soil samples (10.8 %) and two of 12 sediment samples (16.7%). PCB-77 was detected in 6 of 102 floodplain soil samples (5.9%) and was not detected in 12 sediment samples. Two other non-ortho substituted congeners (PCB-81 and PCB-169) were not detected in floodplain soil or sediment samples.

Additionally, the application of TEFs to abiotic media is uncertain. Mammalian TEFs are derived based on prey tissue ingestion (i.e., primarily from oral uptake studies through dietary exposure). Direct calculation of TEQ concentrations in soil and sediment does not account for reductions in bioavailability or uptake that occur differentially for the individual congeners during ingestion, and for differences in the environmental fate of these compounds in abiotic media (Van den Berg et al. 2006[5]). Similarly, the bird and fish TEFs are calculated based on egg injection studies or *in vitro* exposures where the exposure

[5] Concern was expressed [by the World Health Organization Committee] about direct application of the TEF/total TEQ approach to abiotic matrices, such as soil, sediment, etc., for direct application in human risk assessment. This is problematic as the present TEF scheme and TEQ methodology are primarily intended for estimating exposure and risks via oral ingestion (e.g., by dietary intake).

conditions are not likely to be representative (in terms of the suite of congeners and their relative concentrations) of the *in vivo* exposures that result from dietary uptake of dioxins and furans (Van den Berg et al. 1998). Therefore, dioxin TEQs calculated using fish and bird TEFs are relevant only to tissue data for which dioxin/furan congeners were measured. There is significant uncertainty in the application of mammal, bird, and fish TEFs to soil and sediment data in the dietary models, and TEQ HQs for these receptors may not be predictive of actual risk.

## 5.2 Uncertainties Associated with Analytical Methods and Non-Detect Congeners

Soil, sediment, and tissue data analyzed for PCDD/PCDF and DL-PCB congeners were collected between 1999 and 2013. In some samples, especially for DL-PCBs, the laboratory RLs are elevated, resulting in uncertainty in the actual TEQ concentrations. ND congeners were evaluated three different ways in this assessment to estimate a range of possible TEQ concentrations. These include: 1) assuming that all of the ND concentrations are zero; 2) assuming that the ND analytes are present at one-half the RL; and 3) assuming that the PCDD/PCDF ND analytes are present at the RL and that DL-PCB ND analytes are present at 0.5 x RL (i.e., one-half of the RL). As shown on Tables F-1 and F-2, the sediment and soil TEQ concentrations vary depending on the assumptions selected for ND congeners. When ND congeners are evaluated at zero in the TEQ calculation, the TEQ contribution of individual congeners with elevated RLs may be underestimated. As reported by Rushneck et al. (2004), new analytical methods with lower detection limits have shown that some PCB congeners, such as PCB 126, are present in all Aroclor mixtures tested, whereas these congeners had been assumed to not be present in some Aroclor mixtures based on undetectable concentrations measured from older analytical methods.

When ND congeners are evaluated at one-half or the full RL, the TEQ contribution of individual congeners are unlikely to be underestimated but may be overestimated, especially for congeners with elevated RLs. Tables F-1 and F-2 demonstrate that the range of TEQ concentrations calculated for the PCDD/PCDF TEQs is relatively small, because the RLs are generally low. For DL-PCB TEQs, elevated RLs for some congeners result in a larger range of estimated TEQ concentrations. Inclusion of the DL-PCBs in the total TEQ concentrations also results in a relatively wide range of estimated TEQ concentrations compared to the PCDD/PCDF TEQs.

Based on the higher DL-PCB TEQ concentrations calculated using one-half RL concentrations for NDs (Tables F-1 and F-2), it is likely that wildlife HQs greater than one could be estimated for some receptors using the modeled tissue approach for TEQs calculated using one-half ND. However, given the uncertainty in the quantitation of DL-PCBs, as discussed above, it is unclear whether unacceptable risk to wildlife would actually be present. Regardless, the PCB risk assessment presented in this OU-4 BERA is a more robust and less uncertain evaluation of potential risk from PCB exposure than presented herein for DL-PCBs. Potential risk due to PCBs (including DL-PCBs) are more fully evaluated BERA.

## 5.3 Uncertainties Associated with Bioaccumulation of DLCs

The bioaccumulation of PCDDs/PCDFs is influenced by site- and species-specific factors (e.g., trophic level, sediment and soil organic carbon content, organism lipid content); these are discussed in detail by USEPA (2008). Extrapolation of BAFs from one ecosystem to another is a potentially large source of

uncertainty; however, with the exception of the BAFs used for terrestrial invertebrates (from the study by Fagervold et al. 2010), the BAFs used in this assessment were site-specific. There are general uncertainties associated with BAFs and there are uncertainties that are specific to PCDDs/PCDFs. For example, BAF models are considered poor predictors of bioaccumulation of hydrophobic substances from sediment to fish (Usenko et al. 2012). Some of the areas of uncertainty related to bioaccumulation of PCDDs/PCDFs are described below:

- Confounding factors of bioaccumulation models. Bioaccumulation of DLCs and resulting BAFs can be confounded by factors such as the residence time of mobile species within a given exposure unit; the representativeness of the sampling program to assess contaminant concentrations in sediment/soil; the variability in organism rates of biotransformation, metabolism, and excretion; and seasonal food web variations (Usenko et al. 2012). These factors can either overestimate or underestimate exposure to TEQs.
- Assuming PCDD/PCDF and DL-PCB congener concentrations in soil and sediment are 100% bioavailable. Only a fraction of the PCDD/PCDF concentrations present in soil and sediment may be taken up or result in an effect on an organism. Physical, chemical, and biological processes affect contaminant bioavailability, and aging of soil may decrease the bioavailability of dioxins (Ruby et al. 2002); relatively bioavailability for exposure to dioxins from soil is less than 100% (SRC 2010). Therefore, assuming the PCDDs/PCDFs in OU-4 sediment and soil are 100%bioavailable overstates exposure and risk.
- Not accounting for sediment and soil organic carbon content and lipid content of biota. In calculation of BAFs, to account for the partitioning of hydrophobic chemicals, sediment concentrations are often adjusted for organic carbon and tissue concentrations are adjusted for lipid content (Usenko et al. 2012). The BAFs calculated for OU-4 are based on dry weight TEQ concentrations in biota and sediment, consistent with the approach in the OU-4 BERA for PCBs, for which organic carbon normalization did not improve predictability of the uptake models in OU-4.

## 5.4 Uncertainties Associated with the Site-Specific Dataset

The uncertainties associated with the site-specific dataset that was used to assess TEQ risk in OU-4 are discussed below and include the development of EPCs and BAFs.

### 5.4.1 Uncertainties Associated with Selected EPCs

Due to small sample sizes and the methodology used to calculate TEQ EPCs (based on congener concentrations and TEFs), the TEQ EPCs recommended by ProUCL can be sensitive to changes in the number and distribution of samples. For example, the LAA soil dataset consists of 28 samples. The ProUCL-recommended avian DL-PCB TEQ EPC is 4,093 ng/kg, based on the 95% Chebyshev UCL. However, the ProUCL-recommended avian total TEQ EPC is 8,371 ng/kg, based on the 99% Chebyshev UCL, and the same number of samples. For reference, the avian total TEQ EPC based on the 95% Chebyshev UCL is 4,271 ng/kg. This sensitivity in the 95%UCL has a relatively large impact on both the soil and terrestrial tissue EPCs, as can be seen by the difference in HQs estimated by the TU method and direct calculation method. For example, the Carolina wren (1 and 2) would have estimated total TEQ HQs equal to one if the 95% Chebyshev UCL was selected as the EPC.

Additionally, sediment and aquatic tissue EPCs are based predominantly on the maximum concentrations. The small sediment DLC dataset may in result overestimation of risk to aquatic receptors, as a larger dataset would be expected to decrease both variability and use of maximum EPCs.

### 5.4.2 Uncertainties Associated with Selection of Site–Specific and Literature Bioaccumulation Factors for DLC congeners

In addition to the general uncertainties related to bioaccumulation of DLCs, the approach used in this assessment has specific uncertainties that may influence the risk estimates. As discussed in the OU-4 BERA (Section 6.2), tissue data were collected in a subset of the EUs. Additionally, the tissue data were collected within BSAs and were not precisely co-located with sediment/soil data. For TEQ in particular, the site-wide sediment and tissue datasets are small, and the paired data from BSAs available for BAF derivation represent only a subset of that data. In many cases, congener-specific site-wide median BAFs were calculated based just one or two available tissue samples (Table F-6 and Attachment F1). Because some BSAs did not have data for both abiotic and biotic samples, it was not possible to calculate site-wide median BAFs for several congeners and tissues. In these cases, the site-wide average ratio BAF was selected (see Attachment F1). Use of this alternate BAF approach is more uncertain than use of site-wide median BAFs, because the data used to calculate the ratio can be located in any of the BSAs and may not reflect local uptake conditions for the sampled tissue. Further, it is unknown whether the congener-specific BAFs are predictive of tissue concentrations because the BAF datasets are not sufficient for regression analysis. For many congeners, BAFs were not developed because the congener was not detected in tissue. There is uncertainty whether this is due to differences in uptake and elimination of the various congeners and/or whether a larger sample size would increase the number of detected congeners.

Additionally, DLC congeners were not measured in some tissues and therefore BAFs could not be developed. For terrestrial invertebrates, literature BAFs for earthworms from Fagervold et al. (2010) were used to estimate terrestrial prey tissue TEQ concentrations for earthworms, spiders, and terrestrial insects. In the Fagervold et al. (2010) study, BAF values for the earthworm *Eisenia foetida* in untreated soil ranged from 0.02 (dw) for some of the higher chlorinated congeners to 0.17 (dw) for TCDD. Typical BAF values for PCDDs/PCDFs in terrestrial earthworms range from 0.09 to 1.1 (Matscheko et al. 2002). Schrock et al. (1997) found similar ranges (0.09 to 0.28 [dw]) in 28-day bioaccumulation tests of the sandworm *Nereis virens* in dredged sediments. BAF values for other hydrophobic compounds in terrestrial earthworms are generally higher, such as determined in the study by Blankenship et al. (2005), in which BAF values for PCBs in earthworms ranged from 0.48 (dw) to 2.4 (dw) depending on the concentration of PCBs and soil type. Fagervold et al (2010) did not report BAFs for DL-PCB congeners, and therefore the median of the individual PCDD/PCDF congener BAFs was selected. Use of the median PCDD/PCDF BAF to estimate DL-PCB uptake is likely to underestimate uptake of DL-PCBs into earthworm tissue based on comparison to the Blankenship et al. (2005) BAFs, but may over- or under-estimate uptake of DL-PCBs to spiders and terrestrial insects. For aquatic worms, congener-specific BAFs based on Odonate larvae were selected to model uptake. Due to differences in habitat selection and sediment exposure, it is expected that the selected BAFs underestimate exposure to aquatic worms. However, because wildlife receptors consume a mixed diet containing a variety of prey tissue types, the estimated HQs are not expected to be significantly underestimated based on the use of the Odonate BAF for aquatic worms.

Overall, the congener-specific BAFs developed for this TEQ assessment are considered to be highly uncertain and may not accurately reflect site-wide exposure and uptake conditions in OU-4. Use of these BAFs may over- or underestimate TEQ exposure in OU-4.

## 5.5 Uncertainties Associated with Use of Modeled Tissue EPCs

The TEQ risks were based on tissue TEQ concentrations modeled from soil and sediment samples and congener-specific BAFs. Although the risk estimates have a high degree of associated uncertainty, the modeled tissue EPCs provide a better estimate of the range of potential exposure to DLC compounds in OU-4 than use of measured tissue EPCs. For measured tissue, EPCs and associated HQs were not calculated herein because datasets were less than seven samples for all tissue types except forage fish (N=13). As a result, measured tissue EPCs would be based on maximum concentrations, and risk estimates for the entirety of OU-4 would be based on a single tissue sample. To compare the difference between risks estimated using modeled versus measured tissue EPCs, site-wide 95%UCL Avian TEQ concentrations in forage fish were calculated (435, 49.3, and 494 ng/kg dw for PCDD/PCDF TEQ, DL-PCB TEQ, and total TEQ, respectively) and used to estimate risk to belted kingfisher–1, which is assumed to consume 100% forage fish. As shown in Figure F-3, TEQ HQs modeled using sediment data and congener-specific BAFs are generally similar to TEQ HQs calculated using measured tissue EPCs. Thus, at least for piscivorous wildlife, use of the modeled tissue EPCs results in risk estimates that are consistent with risk estimated using measured tissue data.

Additionally, the modeled tissue EPCs were calculated assuming that ND congeners were equal to zero in the tissue TEQ calculation. This assumption may underestimate TEQ concentrations, especially for DL-PCB congeners with elevated reporting limits. However, as the individual DL-PCB congeners generally have low TEF values, the effect on the final modeled TEQ concentration is expected to be minimal. Use of one-half or full RL in the modeled tissue TEQ calculations is not considered appropriate due to the high degree of uncertainty in applying a BAF to a ND concentration.

## 5.6 Uncertainties Associated with TRVs and CTCs

There are always general uncertainties associated with TRV derivation. These uncertainties include, but are not limited to, the following:

- Species-to-species extrapolations and differences in sensitivity
- Lack of data for the appropriate exposure duration
- Targeted effects that may not have been assessed
- Errors in extrapolating data from laboratory to field
- Use of allometric scaling based on body mass (does not account for physiological differences and respective differential sensitivity)
- Acute to chronic extrapolations
- Reliance on LOAELs and NOAELs instead of specified effect levels or dose-response distributions

Using TRVs based on NOAELs, such as in this assessment, is highly conservative and appropriate in a screening assessment to ensure protection of sensitive receptors. The major uncertainties associated with TRVs in this TEQ assessment are discussed below.

- The avian TRV may overstate risks to the Group 3 avian receptors. Farmahin et al. (2013) classified birds based on their sensitivity to DLCs: chicken-like or Group 1 (most sensitive), pheasant-like or Group 2 (intermediate sensitivity, 6-fold lower than Group 1), and quail-like or Group 3 (least sensitive, 35-fold less sensitive than Group 1). Of the nine avian receptors for the OU-4 analysis, the mourning dove, blue jay, spotted sandpiper, and tree swallow were placed in Group 2; the house wren, a species related to the Carolina wren, was also included in Group 2; and the red-tailed hawk, belted kingfisher, great blue heron, and osprey were assigned to Group 3. The Custer et al. (2005) study of the tree swallow provides an appropriately protective TRV for the Group 2 species, but may be overly conservative for and overstate risks to the Group 3 species in the assessment—the red-tailed hawk, belted kingfisher, great blue heron, and osprey.
- Reliance on a highly conservative TRV for mammalian receptors. The TRV for mammalian species was derived from studies of mink. Mink are acknowledged to be uniquely and highly sensitive to the adverse effects of DLCs. Applying this TRV to all mammalian receptors evaluated in the OU-4 assessment is very conservative and overprotective for receptors species that are not as highly sensitive to the effects of DLCs. Recent studies of avian species using advanced technology provide information on the relative sensitivity of various species of birds to the toxic effects of DLCs (refer to Section 2). However, similar studies are not available to assess the relative sensitivity of mammals. Therefore, it is not possible to assess the relative sensitivity of the mammalian receptor species. In addition, the magnitude of the conservative nature of the mammalian risk-based TEQ concentration cannot be quantified; although, using a TRV based on the most sensitive receptor overstates risks for less sensitive mammalian receptors.
- Use of TRVs derived from field studies. Use of a TRV derived from a field study likely reduces the uncertainty associated with extrapolating administered dose (diet) to internal dose. For example, in the case of the avian TRV, if the oral absorption efficiency of DLCs in prey items from the Woonasquatucket River is assumed to be the same as that in prey from OU-4, there would be no uncertainty in the extrapolation of doses. Therefore, there is an advantage to using field-derived TRVs versus those derived from laboratory studies that employ injection or oral gavage as the exposure route. This reduces the uncertainty associated with the derivation of the, and therefore would more accurately reflect risks. However, there are uncertainties inherent in the use of field studies such as the presence and unknown influence of confounding factors such as the effects of other contaminants and other ecological stressors.
- Field studies highlight the overly protective nature of assessment process. In an effort to “ground truth” the predictive ability of ecological benchmarks for a Housatonic River ecological risk assessment, Boonstra and Bowman (2003) evaluated the demography of six local populations of the short-tailed shrew living in eastern deciduous forest palustrine habitat along the Housatonic River on soils contaminated with PCBs. No relationship was found to exist between any shrew demographic parameter and PCB soil concentrations. Shrew densities were high, survival was good, and sex ratio, reproduction rates, growth rates, and body mass were within normal ranges reported in the literature. Thus, these shrew populations showed no detectable impact on their population demography even

though PCB body burdens were 3 to 10 times higher than levels reported in the literature that have been linked with physiological impairment. This suggests that although species may be exposed to (and bioaccumulate) DLCs at relatively high levels, this exposure may not result in population-level effects, and illustrates the potentially great uncertainty associated with predictive risk assessments for DLCs.

- Inclusion of highly sensitive salmonid species in the fish species sensitivity curve that is the basis for the fish CTC. The species sensitivity distribution for use in assessing the risk of TCDD and DLCs incorporates residue effect data for lake trout and other salmonids that are substantially lower than residues associated with effects in the other fish species (Steevens et al. 2005). To account for the inclusion of these sensitive species, which are not present in OU-4, the selected fish TEQ CTC (2.2 ng/g lipid, Section 3.3) is based on the 95%UCL of the effects threshold protective of 90% of the population. Although the mean effect threshold protective of 90% of the population is somewhat lower (0.70 ng/g lipid), fish tissue HQs calculated using the mean effects threshold are all less and or equal to 1 as well (Fish HQs based on the mean CTC increase about three times relative to HQs [Figure F-3] based on the 95%UCL CTC.) Additionally, modeled fish tissue concentrations (Table F-8) for all fish types (forage fish, bottom fish, and predator fish) are below the tissue threshold of 3,000 to 16,000 ng/kg ww (12,000 to 64,000 ng/kg dw) reported by King-Heiden et al. (2012) for wasting/lethality in adult yellow perch (*Perca flavescens*), carp (Cyprinidae) and bullhead (*Ameiurus nebulosus*), adult rainbow trout, bluegill (*Lepomis macrochirus*), and largemouth bass (*Micropterus salmoides*). Therefore, the TRV based on this distribution is not considered to underestimate risk for the less-sensitive fish species that inhabit Choccolocco and Snow Creeks, and would likely overstate risks to these species.

# 6 SUMMARY

The results indicate that OU-4 creek sediments and floodplain soil TEQ concentrations are unlikely to pose an unacceptable risk to wildlife (birds and mammals) or fish, as all NOAEL-based HQs calculated using modeled tissue TEQ concentrations are less than or equal to 1 for PCDD/PCDF TEQ, DL-PCB TEQ, and total TEQ (on a TU basis) calculated using ND=0 (Figure F-2). Soil and sediment PCDD/PCDF TEQ concentrations are also mostly (96 of 102 soils samples and all sediment samples) within the range of background soil concentrations reported in the literature (USEPA 2004, USEPA 2001, BC Environment 1995).

**Notes:**

%: percent
CDD: chlorodibenzo-p-dioxin
CDF: chlorodibenzo-p-furan
DL: dioxin-like
DL-PCB: dioxin-like polychlorinated biphenyl
EPC: exposure point concentration
FOD: frequency of detection
ft bgs: feet below ground surface
HpCDD: heptachlorodibenzo-p-dioxin
HpCDF: heptachlorodibenzofuran
HxCDD: hexachlorodibenzo-p-dioxin
HxCDF: hexachlorodibenzofuran
KM: Kaplan-Meier
mg/kg: milligram per kilogram
n: number of samples
N/A: not applicable
ND: nondetect
ng/kg: nanogram per kilogram
PCDD: polychlorinated dibenzodioxin
PCDF: polychlorinated dibenzofuran
PeCDD: pentachlorodibenzo-p-dioxin
PeCDF: pentachlorodibenzofuran
RPD: relative percent difference
Sd: standard deviation
TCDD: tetrachlorodibenzo-p-dioxin
TCDF: tetrachlorodibenzofuran
TEQ: toxic equivalent
TOC: total organic carbon
UCL: upper confidence limit
µg/kg: microgram per kilogram

**Notes:**
%: percent
CDD: chlorodibenzo-p-dioxin
CDF: chlorodibenzo-p-furan
DL: dioxin-like
DL-PCB: dioxin-like polychlorinated biphenyl
EPC: exposure point concentration
FOD: frequency of detection
ft bgs: feet below ground surface
HpCDD: heptachlorodibenzo-p-dioxin
HpCDF: heptachlorodibenzofuran
HxCDD: hexachlorodibenzo-p-dioxin
HxCDF: hexachlorodibenzofuran
KM: Kaplan-Meier
mg/kg: milligram per kilogram
N/A: not applicable
ND: nondetect
ng/kg: nanogram per kilogram
PCDD: polychlorinated dibenzodioxin
PCDF: polychlorinated dibenzofuran
PeCDD: pentachlorodibenzo-p-dioxin
PeCDF: pentachlorodibenzofuran
RPD: relative percent difference
Sd: standard deviation
TCDD: tetrachlorodibenzo-p-dioxin
TCDF: tetrachlorodibenzofuran
TEQ: toxic equivalent
TOC: total organic carbon
UCL: upper confidence limit
µg/kg: microgram per kilogram

**Table F-6. Summary of Site-Specific BAFs for Dioxin/Furan and Dioxin-like PCB Congeners**
**Anniston PCB Site, Anniston, Alabama**

**Notes:**

[1] Soil and sediment BAFs calculated using soil/sediment Kaplan-Meier Mean in BSA and individual tissue composites (detects only); OU-4 data only.

[2] ave ratio: site-wide average ratio BAF. See Attachment F1 text for details.
median: Sitewide median BAF. See Attachment F1 text for details.

BAF: bioaccumulation factor
BSA: biological sampling area
CDD: chlorodibenzo-p-dioxin
CDF: chlorodibenzo-p-furan
dw: dry weight
KM: Kaplan-Meier
HpCDD: heptachlorodibenzo-p-dioxin
HpCDF: heptachlorodibenzofuran
HxCDD: hexachlorodibenzo-p-dioxin
HxCDF: hexachlorodibenzofuran
N: number of samples
NA: Not available because dioxin/furan congeners were not detected above the laboratory reporting limits in tissue sampl
PCB: polychlorinated biphenyl
PCDD: polychlorinated dibenzodioxin
PCDF: polychlorinated dibenzofuran
PeCDD: pentachlorodibenzo-p-dioxin
PeCDF: pentachlorodibenzofuran
TCDD: tetrachlorodibenzo-p-dioxin
TCDF: tetrachlorodibenzofuran

**Table F-7. Terrestrial Invertebrate BAFs for Dioxin/Furan and Dioxin-like PCB Congeners**
**Anniston PCB Site, Anniston, Alabama**

| Congener | BAF [a] (kg dw/kg dw) | |
|---|---|---|
| **Dioxins** | | |
| 2,3,7,8-Tetrachlorodibenzo-p-dioxin | 0.176 | b |
| 1,2,3,7,8-Pentachlorodibenzo-p-dioxin | 0.0 | b |
| 1,2,3,4,7,8-Hexachlorodibenzo-p-dioxin | 0.0 | b |

| 2,3,3',4,4',5-HxCB (156) | 0.031 | c |
| 2,3,3',4,4',5'-HxCB (157) | 0.031 | c |
| 2,3',4,4',5,5'-HxCB (167) | 0.031 | c |
| 2,3,3',4,4',5,5'-HeCB (189) | 0.031 | c |
| 2,2',4,4',5,5'-HxCB (153) | 0.031 | c |

**Notes:**
Data from Fagervold et al. (2010)
a. BAF calculated from BSAF assuming lipid content (2.3%) and total solids content (32%) from OU-4 earthworms
b. average of available congener-specific BAFs
c. median of available polychlorinated dibenzodioxin/polychlorinated dibenzofuran BAFs
%: percent
BAF: bioaccumulation factor
BSAF: biota-soil accumulation factor
HeCB: hepachlorobyphenyl
HxCB: hexachlorobyphenyl
kg dw/kg dw:kilograms dry weight per kilogram dry weight
PCB: polychlorinated biphenyl
PeCB: pentachlorobiphenyl
TCB: tetrachlorobiphenyl

**Notes:**

%: percent
cdd: chlorodibenzo-p-dioxin
cdf: chlorodibenzo-p-furan
DL: dioxin-like
DL-PCB: dioxin-like polychlorinated biphenyl
dw: dry weight
EPC: exposure point concentration
FOD: frequency of detection
ft bgs: feet below ground surface
hpcdd: heptachlorodibenzo-p-dioxin
hpcdf: heptachlorodibenzofuran
hxcdd: hexachlorodibenzo-p-dioxin
hxcdf: hexachlorodibenzofuran
KM: Kaplan-Meier
mg/kg: milligram per kilogram
ng/kg: nanogram per kilogram
N/A: not applicable
ND: nondetect
ng/kg: nanogram per kilogram
PCDD: polychlorinated dibenzodioxin
PCDF: polychlorinated dibenzofuran
pecdd: pentachlorodibenzo-p-dioxin
pecdf: pentachlorodibenzofuran
RPD: relative percent difference
Sd: standard deviation
tcdd: tetrachlorodibenzo-p-dioxin
tcdf: tetrachlorodibenzofuran
TEQ: toxic equivalent
TOC: total organic carbon
UCL: upper confidence limit

# 1 INTRODUCTION

This attachment to Appendix F of the *Baseline Ecological Risk Assessment for Operable Unit 4* (OU-4 BERA) of the Anniston polychlorinated biphenyl (PCB) Site describes the development of bioaccumulation factors (BAFs) for polychlorinated dibenzo-*p*-dioxin and polychlorinated dibenzofurans (PCDDs/PCDFs) and dioxin-like PCB (DL-PCB) congeners used in the exposure dose calculations to calculate hazard quotients for ecological receptors at OU-4. The OU-4 BERA was conducted to evaluate the aquatic and terrestrial exposure pathways for ecological receptors and potential risks associated with identified constituents of potential concern (COPCs) (PCBs, mercury, barium, chromium, cobalt, lead, and vanadium) within OU-4. PCDDs/PCDFs and DL-PCBs were also evaluated at the request of the United States Environmental Protection Agency (USEPA). Dietary exposure to a range of feeding guilds of birds and mammals was evaluated based on exposure from soil, sediment, and contaminated prey tissues. To evaluate the dietary exposure pathways to aquatic and terrestrial feeding receptors, COPC concentrations in tissues of the prey for the identified receptors were modeled.

The prey items for the representative aquatic receptors selected for evaluation in the OU-4 BERA are aquatic plants, benthic invertebrates, oligochaetes, emergent insects, crayfish, molluscs, frogs, snakes, and fish (represented by forage fish, predator fish, and/or all fish). The prey items for the representative terrestrial receptors selected for evaluation in the OU-4 BERA are terrestrial plants, terrestrial invertebrates (including earthworms, terrestrial- and riparian-feeding spiders, and insects), and small mammals. In addition, some receptors were exposed to a mixed diet of aquatic and terrestrial prey. Section 4 and Appendix B of the OU-4 BERA provide additional details regarding dietary components of the wildlife receptors.

Biotic tissue data and sediment and floodplain soil data were collected as a part of Phase 2 field sampling in 2009. These data were collected primarily to support the evaluation of potential risk to the identified ecological receptors from dietary exposure in OU-4. Details of the approach for this sampling are provided in the *OU-4 Phase 2 Field Sampling Plan* (Arcadis U.S., Inc. [Arcadis] 2009). Additionally, results of Phase I sampling conducted in 2007 at locations near the 2009 Phase 2 tissue and sediment/soil sampling locations are included in the BAF dataset at the request of USEPA (2016). The data collected and used herein are described in Section 2.1 below. As noted below, the datasets available for PCDD/PCDF and DL-PCB BAF development are limited in size.

The bioaccumulation model represents the relationship between the abiotic media (in this case, creek sediment, floodplain soil, and riparian soil) and the measured prey tissue concentration. Although regression analysis is the preferred method to derive uptake relationships predictive of prey tissue concentrations, the PCDD/PCDF and DL-PCB datasets are insufficient for these analyses.

Therefore, prey tissue concentrations were estimated using BAFs that relate concentrations in abiotic media to tissue concentrations through a simple ratio. As a convention herein, ratios based on wet weight or dry weight tissue and abiotic media concentrations are referred to as BAFs. Ratios based on lipid-normalized tissue and organic carbon-normalized sediment are referred to as biota sediment accumulation factors (BSAFs).

As an example, a BAF can be calculated as follows:

Equation 1: $BAF_{insect} = C_{insect} / PCB_s$

where:

$C_{insect}$ Concentration of PCB in insect tissue (milligrams of PCB per kilogram tissue; mg/kg $_{tissue}$)

$PCB_s$ Concentration of PCB in sediment or soil (mg of PCB per kg of sediment or soil; mg/kg $_{sediment\ or\ soil}$)

$BAF_{insect}$ Bioaccumulation factor from sediment-to-insect (kg $_{sediment\ or\ soil}$/kg $_{tissue}$)

When BAFs are used, the predictability of the selected BAF is acknowledged to be uncertain due to the lack of relationship between the soil/sediment and tissue data in a regression analysis.

Congener-specific BAFs were developed to model tissue concentrations of PCDD/PCDF toxic equivalent (TEQ), DL-PCB TEQ, and total TEQ (PCDDs/PCDFs + DL PCBs). The approach for development of BAFs for PCDD/PCDF and DL-PCB congeners is similar to the approach used to develop BAFs for the remaining COPCs, as described in Appendix B. BAF development for PCDD/PCDF and DL-PCB congeners is described in more detail below.

The following sections describe the overall uptake development approach (Section 2) and available data and analyses used to develop PCDD/PCDF and DL-PCB BAFs for aquatic and terrestrial species (Section 3).

# 2 OVERVIEW OF UPTAKE MODEL DERIVATION

## 2.1 Data Use

Three assessment areas (AAs; upper, middle, and lower) were identified within OU-4 based on habitat surveys conducted in a Phase 1 Ecological Survey (Arcadis BBL 2007). Three aquatic biological sampling areas (BSAs) and nine terrestrial BSAs were identified within each of the three AAs for a total of nine aquatic BSAs and 27 terrestrial BSAs within OU-4 that were sampled as part of the 2009 Phase 2 sampling in support of BAF development. Soil and sediment sampling locations are presented on Appendix F Figure F-1. Tissue samples were collected throughout each of the terrestrial and aquatic BSAs (indicated by green hatching on the figure) and were composited. Samples were also collected from three aquatic and three terrestrial reference locations. The terrestrial and aquatic BSAs are also presented in Appendix B Figures B-1a through B-1j.

Because the data are not co-located, soil/sediment samples from the Phase I (2007) and Phase 2 (2009) investigations from locations within or nearby each BSA were grouped and evaluated with the tissue data from the same BSA. Older abiotic media data collected prior to 2007 were not included in the BAF dataset, as surface conditions in the creek, riparian areas, and floodplain may have been altered by physical processes over time. These data groupings were identified by USEPA (2016) for use in BAF development, and are summarized in Table F1-1 for sediment and Table F1-2 for soil. As indicated in the tables, only a subset of the samples was analyzed for PCDDs/PCDFs and DL-PCBs.

The BAF datasets were insufficient for regression analysis. Site-wide median BAFs were calculated for each PCDD/PCDF and DL-PCB congener, as described below.

## 2.2 Site-wide Median BAF Calculation

For the site-wide median BAFs, all soil/sediment data, including detected and non-detected results, for the BSAs were included in the evaluation. The mean abiotic media concentration was calculated for each BSA using Kaplan-Meier (KM) statistics to account for any non-detected results. Only detected concentrations in tissue were included in the BAF calculations. BAFs were calculated for each OU-4 BSA using the following approach:

1. Calculate individual tissue sample BAFs ($BAF_i$) using KM mean soil/sediment concentration for the BSA, individual tissue sample concentration, and Equation 1.
2. Calculate median of the $BAF_i$ for all individual samples taken from OU-4, which resulted in a congener-specific site-wide median BAF used to model uptake. Reference BSAs are not included in the median BAF calculation.
3. If data were not sufficient to calculate a site-wide median BAF:
    a. If a COPC was detected in OU-4 tissue, but data for soil/sediment in the same BSA were lacking, the site-wide average ratio BAF was calculated by dividing the site-wide average detected tissue concentration by the average KM mean concentrations for the BSAs.

b. If a congener was never detected in OU-4 tissue, no BAF was selected. The congener was excluded from the TEQ calculations. As a result, exposure to PCDDs/PCDFs and DL-PCBs was evaluated based only on congeners detected in OU-4 prey tissue.

## 2.3 Literature Uptake Relationships

PCDD/PCDF tissue data were not available for terrestrial insects (grasshoppers/crickets), spiders/detritivores, and earthworms. For these receptors, uptake of PCDD/PCDF and DL-PCB congeners was modeled using a literature uptake factor.

For earthworms, BAFs were based on data from Fagervold et al. (2010). The biota to soil accumulation factors (BSoAFs) for PCDD/PCDF congener uptake by earthworms from the study by Fagervold et al. (2010) were used. In the Fagervold et al. (2010) study, BSoAF values (kg organic carbon/kg lipid) for the earthworm *Eisenia foetida* in untreated soil ranged from 0.02 for some of the higher chlorinated congeners to 0.17 for tetrachlorodibenzo-p-dioxin. The BSoAF values were converted to BAFs based on a dry weight basis using organic carbon content reported by Fagervold et al. (2010) and lipid (2.3 percent) and solids content (32 percent) for OU-4 earthworms. The BAFs for PCDD/PCDF congener uptake by earthworms from the Fagervold et al. (2010) study were used as the BAFs for earthworms in the OU-4 BERA (Table F1-3). The earthworm BAFs were also selected to estimate uptake into spiders and terrestrial insects, as site data for these prey tissues are lacking.

For the DL-PCB congeners, soil and sediment data from the BSAs with tissue data were not available, and literature uptake data are generally lacking. The median of the PCDD/PCDF congener BAFs from the Fagervold et al. (2010) study was selected to estimate uptake into earthworms for all DL-PCB congeners (Table F1-3), such that earthworm BAFs for both PCDD/PCDFs and DL-PCBs were based on literature uptake values.

# 3 BAFS FOR PCDD/PCDF AND DL-PCB CONGENERS

Median BAFs were calculated using the approach described in Section 2.2. PCDD/PCDF and DL-PCB congeners were not detected in all soil and sediment samples; therefore, the abiotic media concentration was the KM mean concentration for the BSA. Because many tissues had congener concentrations below the laboratory reporting limit and because some BSAs did not have data for both abiotic and biotic samples, it was not possible to calculate median BAFs for many congeners and tissues. The grouped tissue and soil/sediment data and resulting site-wide median BAFs are calculated in Tables F1-4a and b for aquatic receptors and Table F1-5 for terrestrial receptors. When congeners were detected in tissue but soil/sediment data were not available for the same BSA (i.e., congener-specific median BAF could not be calculated), a congener-specific site-wide average BAF was calculated by dividing the site-wide average detected tissue concentration by the site-wide average KM mean soil or sediment concentrations for the BSAs. When congeners were never detected in tissue, no BAF was selected. The site-specific BAF values and corresponding calculation type (congener-specific site-wide median BAF or congener-specific average ratio BAF) are summarized in Table F1-6.

For aquatic oligochaetes, tissue data for PCDDs/PCDFs and DL-PCBs are not available. Consistent with the approach in the OU-4 BERA for non-mercury metals, BAFs for aquatic oligochaetes were based on benthic invertebrate (Odonata) tissue.

For earthworms, spiders, and terrestrial insects, BAFs from the Fagervold et al. (2010) study were used (Table F1-3).

The selected BAFs were used along with avian, mammalian, and fish toxicity equivalency factors from the World Health Organization (Van den Berg et al. 1998 and 2006, as cited in USEPA 2008) to estimate TEQ concentrations in prey tissues. PCDD/PCDF TEQ, DL-PCB TEQ, and total TEQ concentrations in prey tissues, including aquatic plants, aquatic emergent and flying insects, reptiles, amphibians, fish, aquatic benthic invertebrates (Odonata larvae), crayfish, molluscs, small mammals, and terrestrial plants, were calculated.

**Notes:**
Data from Fagervold et al. (2010)
a. BAF calculated from BSAF assuming lipid content (2.3%) and total solids content (32%) from OU-4 earthworms.
b. average of available congener-specific BAFs
c. median of available polychlorinated dibenzodioxin/polychlorinated dibenzofuran BAFs
%: percent
BAF: bioaccumulation factor
BSAF: biota-soil accumulation factor
HxCB: hexachlorobiphenyl
NA: not available
kg dw/kg dw: kilogram dry weight per kilogram dry weight
kg OC/kg lipid: kilogram organic carbon per kilogram lipid
PeCB: pentachlorobiphenyl
TCB: tetrachlorobiphenyl
TOC: total organic carbon

**Notes:**

a. PCDD/PCDF congener data are presented in pg/g dry weight.
Dioxin-like PCB congener data are presented in mg/kg dry weight.

BAF: bioaccumulation factor
dw: dry weight
CDD: chlorodibenzo-p-dioxin
CDF: chlorodibenzo-p-furan
HpCDD: heptachlorodibenzo-p-dioxin
HpCDF: heptachlorodibenzofuran
HxCDD: hexachlorodibenzo-p-dioxin
HxCDF: hexachlorodibenzofuran
KM: Kaplan-Meier
mg/kg: milligrams per kilogram
NA: not applicable
ND: nondetect
PCB: polychlorinated biphenyl
PCDD: polychlorinated dibenzodioxin
PCDF: polychlorinated dibenzofuran
PeCDD: pentachlorodibenzo-p-dioxin
PeCDF: pentachlorodibenzofuran
pg/g: picograms per gram
TCDD: tetrachlorodibenzo-p-dioxin
TCDF: tetrachlorodibenzofuran

**Notes:**

a. PCDD/PCDF congener data are presented in pg/g dry weight.
Dioxin-like PCB congener data are presented in mg/kg dry weight.

BAF: bioaccumulation factor
dw: dry weight
CDD: chlorodibenzo-p-dioxin
CDF: chlorodibenzo-p-furan
HpCDD: heptachlorodibenzo-p-dioxin
HpCDF: heptachlorodibenzofuran
HxCDD: hexachlorodibenzo-p-dioxin
HxCDF: hexachlorodibenzofuran
KM: Kaplan-Meier
mg/kg: milligrams per kilogram
NA: not applicable
ND: nondetect
PCB: polychlorinated biphenyl
PCDD: polychlorinated dibenzodioxin
PCDF: polychlorinated dibenzofuran
PeCDD: pentachlorodibenzo-p-dioxin
PeCDF: pentachlorodibenzofuran
pg/g: picograms per gram
TCDD: tetrachlorodibenzo-p-dioxin
TCDF: tetrachlorodibenzofuran

**Notes:**

a. PCDD/PCDF congener data are presented in pg/g dry weight.
Dioxin-like PCB congener data are presented in mg/kg dry weight.

BAF: bioaccumulation factor
dw: dry weight
CDD: chlorodibenzo-p-dioxin
CDF: chlorodibenzo-p-furan
HpCDD: heptachlorodibenzo-p-dioxin
HpCDF: heptachlorodibenzofuran
HxCDD: hexachlorodibenzo-p-dioxin
HxCDF: hexachlorodibenzofuran
KM: Kaplan-Meier
mg/kg: milligrams per kilogram
NA: not applicable
ND: nondetect
PCB: polychlorinated biphenyl
PCDD: polychlorinated dibenzodioxin
PCDF: polychlorinated dibenzofuran
PeCDD: pentachlorodibenzo-p-dioxin
PeCDF: pentachlorodibenzofuran
pg/g: picograms per gram
TCDD: tetrachlorodibenzo-p-dioxin
TCDF: tetrachlorodibenzofuran

**Notes:**

[1] Soil and sediment BAFs calculated using soil/sediment Kaplan-Meier Mean in BSA and individual tissue composites (detects only);

[2] ave ratio: site-wide average ratio BAF.
median: Sitewide median BAF.

BAF: bioaccumulation factor
BSA: biological sampling area
CDD: chlorodibenzo-p-dioxin
CDD: chlorodibenzo-p-furan
dw: dry weight
KM: Kaplan-Meier
HpCDD: heptachlorodibenzo-p-dioxin
HpCDF: heptachlorodibenzofuran
HxCDD: hexachlorodibenzo-p-dioxin
HxCDF: hexachlorodibenzofuran
N: number of samples
NA: Not available because dioxin/furan congeners were not detected above the laboratory reporting limits in tissue samples.
PCB: polychlorinated biphenyl
PCDD: polychlorinated dibenzodioxin
PCDF: polychlorinated dibenzofuran
PeCDD: pentachlorodibenzo-p-dioxin
PeCDF: pentachlorodibenzofuran
TCDD: tetrachlorodibenzo-p-dioxin
TCDF: tetrachlorodibenzofuran

**Notes:**
All units in nanograms per kilogram dry weight (ng/kg dw)
Non-detect congeners evaluated at zero for TEQ calculations
%: percent FOD: frequency of detection Sd: standard deviation UCL: upper confidence limit
EPC: exposure point concentration ng/kg dw: nanograms per kilogram dry weight TEQ: toxic equivalent
